# Profit Margins in U.S. Domestic Airline Routes\*

Hakan Yilmazkuday<sup>†</sup>

November 11, 2021

## Abstract

This paper estimates profit margins in the U.S. airline industry at the domestic route level. The dynamic estimation methodology used not only is robust to any simultaneity/endogeneity bias by construction but also results in profit margin estimates that are highly consistent with actual profit data from the U.S. airline industry. Estimated annual profit margins have an average of about 13.3%, with a range between 2.7% and 42.9% across routes. A cross-route analysis further suggests that annual profit margins increase with the market share of the largest airline serving the route, whereas they decrease with airfare. Important policy suggestions follow.

**JEL Classification:** C32, L93

**Key Words:** Profit Margin; Price Elasticity; U.S. Domestic Routes.

# 1 Introduction

One-way airfare between Seattle, WA and Yakima, WA has been about \$103, while it has been about \$402 between New York City, NY and Monterey, CA, on average between 2000-2017.<sup>1</sup> Although these airfares might have been determined by several market conditions, which of these routes have higher profit margins?<sup>2</sup> Answering this question is important not only for this particular route but also for any other one, because consumer welfare and thus optimal policy against excessive usage of market power by airlines highly depend on the answer (e.g., see [Brons, Pels, Nijkamp, and Rietveld \(2002\)](#)). Airlines also manage their fleet and determine their investment plans to expand or shrink their facilities based on this critical information (e.g., see [Valdes \(2015\)](#)); moreover, even airplane designs are achieved based on these details (e.g., see [Carson, Cenesizoglu, and Parker \(2011\)](#)).

This paper estimates profit margins for individual domestic routes within the U.S. by using quarterly data between 2000 and 2017. As the data set used is at the domestic-route level, (i) estimated profit margins represent the average measures across airlines of that route, although multiple airlines may be serving in a particular route, and (ii) the information is averaged out regarding direct versus indirect flights. The estimation is achieved by using implications of the Lerner markup rule in a structural vector autoregression (SVAR) model. This corresponds to estimating the inverse price elasticity of demand for each route in a dynamic framework as it represents the profit margin in the Lerner markup rule, which is consistent with studies such as by [Brons, Pels, Nijkamp, and Rietveld \(2002\)](#) who have suggested using time series data in the estimation of elasticity measures.

---

<sup>1</sup>The source for these values is described in the data section.

<sup>2</sup>The answer for the particular route is given in the conclusion section of this paper.

The estimation of profit margins for each route is achieved by using the textbook definition of the inverse price elasticity of demand, which is the percentage change in airfare divided by the percentage change in the number of passengers. Since profit maximization is achieved by choosing the number of passengers according to the Lerner markup rule, in the context of the SVAR model, profit margins are estimated as the cumulative response of airfares divided by the cumulative response of passenger numbers, both following a shock on the number of passengers after controlling for changes in airline costs. This approach is robust to any simultaneity/endogeneity bias by construction (due to allowing for changes in both airfare and passenger numbers, following a structural shock), which is the main contribution of the paper.

Regarding the level of aggregation, this paper uses time-series data for each U.S. domestic route individually. This is similar to earlier studies such as by [Abrahams \(1983\)](#), [Jorge-Calderón \(1997\)](#), [Abate \(2016\)](#) and [Hakim and Merkert \(2019\)](#) who have also used route-level data to estimate profit margins or price elasticity measures. Exceptions are studies such as by [Mumbower, Garrow, and Higgins \(2014\)](#) who have used data from a single airline, JetBlue, or by [Morlotti, Cattaneo, Malighetti, and Redondi \(2017\)](#) who have used data from another single airline, easyJet; these studies have estimated higher price elasticity measures with respect to other studies using route-level data, consistent with previous research suggesting that higher aggregation (e.g., route-level data) results in lower price elasticity measures.

As SVAR estimations are achieved at the route level, price elasticity measures and profit margins are estimated for each route individually. This results in having only one estimate for each route representing the quarterly sample period between 2000 and 2017. These route-specific estimates are further used in a secondary analysis to investigate whether the

heterogeneity across routes can be explained by other factors such as airfares (as in Fischer and Kamerschen (2003)), lower distance (as in Kutlu and Sickles (2017)) or higher airline market shares (as in Bailey, Graham, Graham, and Kaplan (1985), Hurdle, Johnson, Joskow, Werden, and Williams (1989), Berry (1990), Berry (1992), Borenstein (1990), Borenstein (1991), Brueckner, Dyer, and Spiller (1992), or Evans, Kessides, et al. (1993)). The results of this secondary analysis are further used to have certain policy suggestions regarding consumer welfare and airline profits.

Overall, this paper contributes to the literature through the estimation methodology that takes into account the dynamic relationship between airline costs, airfares, and the number of passengers. To our knowledge, this is the first paper using such an approach that has several benefits. Specifically, the SVAR model used for the estimation considers the simultaneous relationship between airline costs, airfares, and the number of passengers by using quarterly data at the domestic-route level so that any endogeneity between these variables are controlled for in a dynamic way by construction.

Another contribution of the paper is through considering the reaction of variables to each other through impulse response functions. This contribution due to using a time-series approach (of SVAR) results in estimating a causal relationship between percentage changes in airfares and percentage changes in passenger numbers, where airline costs are controlled for. This is different from the existing literature that ignores the causality between these variables due to using cross-sectional regressions. This contribution results in estimating annual profit margins that are highly similar to those implied by actual profit data obtained from the U.S. domestic airline industry.

This paper also contributes by estimating the profit margin and price elasticity of demand for each U.S. domestic route individually. These route-specific estimates (representing the overall sample period) that are obtained by the SVAR model are further used in a secondary cross-sectional analysis to explain why certain routes have higher or lower profit margins or price elasticity measures. Based on this contribution, important policy implications follow both at the national and the domestic-route levels (as discussed in details at the end of this paper).

The rest of the paper is organized as follows. The next section motivates the SVAR model by using the implications of the Lerner markup rule. Section 3 introduces the data set used, where descriptive statistics are discussed. Section 4 reveals the estimation results based on the SVAR model, while Section 5 depicts the results of a secondary investigation based on the comparison across routes. Section 6 concludes with discussing the corresponding policy implications. Route-specific and city-specific empirical results are given in the Online Appendix.

## 2 Empirical Methodology

The estimation is achieved by using implications of the Lerner markup rule in a SVAR model. Our objective is to estimate profit margins in the U.S. domestic airline market by focusing on individual routes across U.S. cities based on *pricing-to-market*. For the market between any two U.S. cities, profit margins are measured by using implications of the Lerner markup rule. The motivation behind using the Lerner markup rule is that when the (inverse) price

elasticity of market demand is known, the corresponding profit margins are can be obtained by using the implications of the Lerner markup rule.

## 2.1 The Model

The main objective in this subsection is to have a theoretical motivation to estimate the (inverse) price elasticity of market demand at the domestic-route level so that the corresponding profit margins can be obtained. In formal terms, for the market between any two U.S. cities,  $i$  and  $j$ , the profit function  $\pi_{ij}$  is given by:

$$\pi_{ij} = P_{ij}(Q_{ij}) \times Q_{ij} - C_{ij}(Q_{ij}) \quad (1)$$

where  $P_{ij}(Q_{ij})$  represents the *inverse* demand function of the market between U.S. cities  $i$  and  $j$ , with  $P_{ij}$  representing the corresponding airfare depending on the number of passengers  $Q_{ij}$  in this route, and  $C_{ij}(Q_{ij})$  represents total cost of this market, also depending on  $Q_{ij}$ .

Profit maximization based on *pricing-to-market* is achieved by choosing route-specific  $Q_{ij}$ , which results in the Lerner markup rule of  $\frac{P_{ij} - MC_{ij}}{P_{ij}} = \varepsilon_{ij}$ , where  $MC_{ij} = \frac{\partial C_{ij}(Q_{ij})}{\partial Q_{ij}}$  represents marginal costs, and  $\varepsilon_{ij} = -\frac{\partial P_{ij}(Q_{ij})}{\partial Q_{ij}} \frac{Q_{ij}}{P_{ij}}$  represents the *inverse* price elasticity of market demand that satisfies  $0 < \varepsilon_{ij} < 1$  (which ensures that the market continues operating). In this framework,  $\varepsilon_{ij}$  further corresponds to the profit margin due to  $\frac{P_{ij} - MC_{ij}}{P_{ij}} = \varepsilon_{ij}$ . Finally, the price elasticity of demand  $\eta_{ij}$  is given by  $\eta_{ij} = \frac{1}{\varepsilon_{ij}}$ .

## 2.2 Estimation

Based on the Lerner markup rule, the pricing (and thus supply) decision of the airline industry represented by the equilibrium airfare depends on airline costs, whereas the demand coming from passengers depends on the airfare (determined by airline costs). These details can be captured in a dynamic framework by using implications of the SVAR model of  $z_{ijt} = (\Delta c_{ijt}, \Delta p_{ijt}, \Delta q_{ijt})'$ , where  $\Delta c_{ijt}$  is the percentage change in airline costs,  $\Delta p_{ijt}$  is the percentage change in airfares, and  $\Delta q_{ijt}$  is the percentage change in number of passengers, all for the market between U.S. cities  $i$  and  $j$ . Since the model considers percentage changes of variables over time, any route-specific characteristic (including route-specific taxes, route-specific airport chargers, route-specific service quality, route-specific hubs) that are constant over time are controlled for by construction.

For the market between U.S. cities  $i$  and  $j$ , the estimation is achieved by using the SVAR model given by:

$$A_{ijo} z_{ijt} = a_{ij} + \sum_{k=1}^4 A_{ijk} z_{ijt-k} + u_{ijt} \quad (2)$$

where  $u_{ijt}$  is the vector of serially and mutually uncorrelated structural innovations. For estimation purposes, the model is expressed in reduced form as follows:

$$z_{ijt} = b_{ij} + \sum_{k=1}^4 B_{ijk} z_{ijt-k} + e_{ijt} \quad (3)$$

where  $b_{ij} = A_{ijo}^{-1} a_{ij}$ ,  $B_{ijk} = A_{ijo}^{-1} A_{ijk}$  for all  $k$ , and it is postulated that the structural impact multiplier matrix  $A_{ijo}^{-1}$  has a recursive structure such that the reduced form errors  $e_{ijt}$  can be

decomposed according to  $e_{ijt} = A_{ijo}^{-1}u_{ijt}$ , where the sizes of shocks are standardized to unity (i.e., the identification is by triangular factorization).

The recursive structure imposed on  $A_{ijo}^{-1}$  requires an ordering of the variables used in the estimation for which we use the ordering already given in  $z_{ijt}$  above as it is consistent with the Lerner markup rule. In particular, (i) airline costs are taken as given by the airline market and thus they do not respond to shocks in airfares or passenger numbers, neither initially nor in the long-run, where the latter is achieved by using block exogeneity; (ii) airfares respond to airline costs initially due to the airline market using the Lerner markup rule for pricing; and (iii) number of passengers responds to both airfares and airline costs due to market conditions.

The estimation is achieved for individual U.S. domestic routes (each represented by a city pair  $ij$ ) using a Bayesian approach with independent normal-Wishart priors. This corresponds to generating posterior draws for the structural model parameters by transforming each reduced-form posterior draw. In particular, for each draw of the covariance matrix from its posterior distribution, the corresponding posterior draw for  $A_{ijo}^{-1}$  is constructed by using by triangular factorization so that the sizes of shocks are standardized to unity. In the Bayesian framework, a total of 2,000 samples are drawn, where a burn-in sample of 1,000 draws is discarded. The remaining 1,000 draws are used to determine the structural impulse responses that are necessary for the estimation of profit margins and price elasticity measures.

## 2.3 Implications for Profit Margins

When variables are represented in percentage changes as in this paper, the *inverse* price elasticity of demand  $\varepsilon_{ij}$ , which also represents the profit margin for the market between

U.S. cities  $i$  and  $j$ , can be rewritten as percentage changes in airfares divided by percentage changes in number of passengers:

$$\overbrace{\varepsilon_{ij} = \frac{P_{ij} - MC_{ij}}{P_{ij}} = -\frac{\partial P_{ij}(Q_{ij})}{\partial Q_{ij}} \frac{Q_{ij}}{P_{ij}} = \underbrace{-\frac{\Delta p_{ijt}}{\Delta q_{ijt}}}_{\text{Cumulative Responses in SVAR}}}_{\text{Implications of the Lerner Markup Rule}} \quad (4)$$

where percentage changes can be measured following the effects of a change in the number of passengers, because profits are maximized in airline markets by choosing the number of passengers as in Equation 1. In terms of the SVAR model, this corresponds to the ratio of the cumulative impulse response of airfares divided by the cumulative impulse response of passenger numbers, both following a shock on the number of passengers.

Since cumulative impulses can be calculated for any period after the shock, annual profit margins  $\varepsilon_{ij}$ 's for the city pair  $ij$  can be estimated in one year (i.e., four quarters) following a shock on the number of passengers. This approach is robust to any simultaneity problem between airfares and number of passengers due to allowing for changes in both airfare and passenger numbers, following a structural shock. The estimated  $\varepsilon_{ij}$ 's can further be used to obtain the price elasticity of demand  $\eta_{ij} = \frac{1}{\varepsilon_{ij}}$  measures. In the Bayesian estimation,  $\varepsilon_{ij}$ 's and  $\eta_{ij}$ 's are calculated for each of the 1,000 draws, and the draws that satisfy  $0 < \varepsilon_{ij} < 1$  (to be consistent with the implications of the Lerner markup rule) are used to construct the distribution of each estimate. While the median of each distribution is considered as the corresponding Bayesian estimator, the 16th and 84th quantiles of distributions are used to construct the 68% credible intervals.

### 3 Data Set

Data on airfare and number of passengers have been obtained from the U.S. Department of Transportation (DOT) under the title of "Contiguous State City-Pair Markets That Average At Least 10 Passengers Per Day." These consist of average one-way airfare and average one-way daily number of passengers between any two cities within the U.S. with at least ten passengers per day, where the direction of the route is not considered. A typical observation is for the route between Albany, NY and Chicago, IL that has an average (over our sample period) one-way airfare of \$205 and an average one-way daily passenger number of 312. Due to our data covering U.S. domestic routes (rather than specific airlines), the estimated results will represent average values across airlines in particular routes. This data set also includes the distance between the cities covered as well as the market share of the largest airline in that market.

Airline costs are measured by "Passenger Airline Cost Index (PACI)" obtained from Airlines for America.<sup>3</sup> This index measures the cost of inputs for passenger airlines (e.g., labor, fuel, food, aircraft ownership, airport landing fees, insurance, utilities, interest) to the provision of air service over time. The vast majority of PACI is derived from quarterly financial and operational information collected by DOT (principally, Form 41 reports); it reflects all U.S. passenger airlines filing complete reports.<sup>4</sup>

Since our estimation methodology requires continuous data during the sample period, we focus on 2,992 routes (each represented by a city pair) for which such data are available. Such an approach is also consistent with the restriction of  $0 < \varepsilon_{ij} < 1$  which ensures that

---

<sup>3</sup>Their web page is <http://airlines.org/>.

<sup>4</sup>Further technical details about PACI can be found at <https://www.airlines.org/dataset/a4a-quarterly-passenger-airline-cost-index-u-s-passenger-airlines>.

the market continuous operating regarding its profitability. The quarterly sample period between 2000Q1 and 2017Q4 has been chosen to be consistent with data availability. In the estimation, all variables are represented as demeaned annual percentage changes measured by quarterly year-on-year log changes that are robust to any seasonality concern by construction.

The summary of series that enter estimations is given in Figure 1, where the average airfare (across 2,992 U.S. domestic routes) is highly correlated with airline costs in terms of their annual percentage changes. When variation across routes is considered, the standard deviation of airfares is highly correlated with that of passenger numbers across routes, suggesting that route-specific dynamics are important to consider, as we achieve in this paper.

The average (over time) distributions of airfare, number of passengers, market share of the largest airline, and distance are also given in Figure 1, and they are summarized in Table 1 across routes. As is evident, airfares have an average (across routes) of about \$226 between any two U.S. cities (on average over time), although they range between \$96 (representing the route between Greensboro/High Point, NC and Salt Lake City, UT) and \$434 (representing the route between Richmond, VA and Tampa, FL). Number of passengers have an average of about 313, with a range between 16 (representing the route between Fargo, ND and Kansas City, MO) and 19,336 (representing the route between Los Angeles, CA and San Francisco, CA).

## 4 Estimation Results

Individual estimates (2,992 of them) are achieved for each U.S. domestic route in the sample. Since profit margins and price elasticity measures can be estimated for any period following

a shock on the number of passengers (as shown in Equation 4), we obtain annual estimation results as those obtained one year (four quarters) after the shock. Due to our data covering U.S. domestic routes (rather than specific airlines), the estimated results represent average values across airlines in particular routes. The following subsections reveal the details.

## 4.1 Profit Margin Estimates

Estimates of annual profit margins are summarized in Table 2 and Figure 2 in percentage terms, while route-specific estimates are given in Online Appendix Table A.1. Profit margins have an average of about 13.3%, with a range between 2.7% (for the route between San Francisco, CA and St. Louis, MO) and 42.9% (for the route between Lexington, KY and Orlando, FL) across routes.

The average (across routes) estimates of profit margins are in line with actual data sets provided for the overall U.S. air transport sector. For example, according to Airlines for America, the U.S. airline industry has profit margins ranging between 12.1% and 15.6% between 2015 and 2017.<sup>5</sup> Likewise, according to IATA Industry Statistics, the airline industry in North America has operating margins ranging between 6.8% and 14.4% between 2013 and 2017.<sup>6</sup> Similarly, according to Damodaran Online, the U.S. air transport sector has an annual after-tax operating margin (corresponding to the profit margin in this paper) of about 7% on average between 2000-2017 (i.e., the sample period in this paper).<sup>7</sup>

Even though the average (across routes) profit margins in this paper representing the U.S. domestic airline market are in line with the U.S. air transport sector data, they are

---

<sup>5</sup>The web page of Airlines for America is <http://airlines.org/>.

<sup>6</sup>The web page of IATA Industry Statistics is <https://www.iata.org/>.

<sup>7</sup>The web page of Damodaran Online is <http://pages.stern.nyu.edu/~adamodar/>.

lower compared to the literature. For example, studies such as by [Berry and Jia \(2010\)](#) have suggested profit margins for the U.S. airline industry ranging between 41% and 78% across different model specifications. Since the results of this paper are consistent with the actual profit data, the difference between earlier studies and this paper can be attributed to alternative estimation methodologies and sample periods.

## 4.2 Price-Elasticity Estimates

Price elasticity estimates are also summarized in Table 2 and Figure 2, while route-specific estimates are given in the Online Appendix Table A.1. Price elasticity estimates have an average (across routes) of about 9, with a range between 2.3 (for the route between Lexington, KY and Orlando, FL) and 39.6 (for the route between San Francisco, CA and St. Louis, MO).

Our price elasticity estimates, which are consistent with actual profit data due to their implications for profit margins as discussed above, are nevertheless higher compared to the existing literature. In their survey of studies, both [Brons, Pels, Nijkamp, and Rietveld \(2002\)](#) and [Gillen, Morrison, and Stewart \(2003\)](#) have shown that price elasticity measures have an average of about 1.1 across studies, with the highest value of 3.2; [Berry and Jia \(2010\)](#) have suggested price elasticity measures ranging between 1.6 and 2; [Chi and Baek \(2012\)](#) have estimated a long-run elasticity of about 5.6; [Mumbower, Garrow, and Higgins \(2014\)](#) have estimated elasticities ranging between 1.3 and 2; and [Kutlu and Sickles \(2017\)](#) have estimated elasticities ranging between 1.7 and 2.8.<sup>8</sup> Since the results of this paper are consistent with

---

<sup>8</sup> Also see earlier studies such as by [Brander and Zhang \(1990\)](#), [Brander and Zhang \(1993\)](#) or [Oum, Zhang, and Zhang \(1993\)](#) who have considered route-specific profit or elasticity measures in their investigations.

the actual profit data, once again, the difference between earlier studies and this paper can potentially be connected to alternative estimation methodologies and sample periods.

## 5 Distribution of Profit Margins across Routes

After having profit margin estimates for each route (within the U.S.) in our sample, following studies such as by Borenstein (1989), Lijesen, Nijkamp, and Rietveld (2002), Fischer and Kamerschen (2003) and Fageda, Jiménez, and Díaz (2012), we would like to know how much they are affected by certain route characteristics, such as average airfare, average number of passengers, market share of the largest airline, or distance. Since city characteristics may also have impacts on profit margins (e.g., due to higher/lower demand conditions or airport costs, as in studies such as by Borenstein (1989), Dobruszkes, Lennert, and Van Hamme (2011) or Fageda, Jiménez, and Díaz (2012)), we control for (and measure) city-specific effects. Accordingly, we regress profit margins in percentage terms (i.e.,  $100 \times \varepsilon_{ij}$ ) on log average airfare, log average number of passengers, market share of the largest airline, and log distance in different regression specifications by including city fixed effects, since these route characteristics may be correlated with each other. Therefore, our objective is mostly to show how profit margins are correlated with any of these individual route characteristics, after controlling for city characteristics.

Univariate regression results based on route characteristics are given in Table 3 for profit margins, where Ordinary Least Squares (OLS) is used for cross-sectional estimations. As is evident, after controlling for city fixed effects, profit margins decrease with airfare and they increase with market share, independent of the regression considered. Profit margins decrease

with the number of passengers when all variables are used as right-hand-side variables at the same time, whereas they decrease with distance when only distance is considered as the right-hand-side variable. Focusing on the significant effects, after controlling for only city fixed effects, doubling airfare across routes results in about 1.4% lower profit margins, doubling the market share of the largest airline results in about 3.1% higher profit margins, and doubling distance results in about 0.9% lower profit margins.

Compared to the existing literature, having negative effects of average airfare on profit margins is consistent with studies such as by [Fischer and Kamerschen \(2003\)](#), whereas having negative effects of distance on profit margins is consistent with studies such as by [Kutlu and Sickles \(2017\)](#).<sup>9</sup> Similarly, having positive effects of market share on profit margins is consistent with studies such as by [Bailey, Graham, Graham, and Kaplan \(1985\)](#), [Hurdle, Johnson, Joskow, Werden, and Williams \(1989\)](#), [Berry \(1990\)](#), [Berry \(1992\)](#), [Borenstein \(1990\)](#), [Borenstein \(1991\)](#), [Brueckner, Dyer, and Spiller \(1992\)](#), or [Evans, Kessides, et al. \(1993\)](#).

Nevertheless, focusing on univariate regressions can result in the omitted variable bias. Accordingly, when all variables are included at the same time, the results are given in the last column of Table 3. As is evident, after controlling for city fixed effects and focusing on the significant effects, doubling airfare across routes results in about 2.8% lower profit margins, and doubling the market share of the largest airline results in about 2.7% higher profit margins. These results are also supported by relatively high  $R$ -squared values. However, log distance becomes insignificant when all variables are included in the regression (as in

---

<sup>9</sup>Studies such as by [Brander and Zhang \(1990\)](#) have shown how average costs decline with distance due to certain fixed costs. When this observation is considered together with the results in this paper (showing that profit margins decrease with distance), it is implied that demand is lower for routes with longer distance measures.

studies such as by [Brons, Pels, Nijkamp, and Rietveld \(2002\)](#)), suggesting that it may be correlated with (or the determinant of) log airfare.<sup>10</sup> We next investigate this possibility further.

Specifically, while investigating the determinants of profit margins, airfares can be affected by distance, number of passengers or market share. To address this issue, an alternative set of regressions is considered for robustness, this time by using Two-Stage Least Squares (TSLS) to consider potential endogeneity concerns. The corresponding results are given in Table 4, where, for further robustness, regressions (1) and (2) consider log distance as an instrument for log airfare, and regression (3) considers log distance, log passenger and market share as instruments for log airfare. As is evident, profit margins decrease with airfare, independent of the regression specification considered. Therefore, the results are robust to the consideration of the relationship between airfare and other variables.

We also run separate regressions of profit margins in percentage terms only on city fixed effects to measure the contribution of city characteristics as in studies such as by [Borenstein \(1989\)](#), [Dobruszkes, Lennert, and Van Hamme \(2011\)](#) or [Fageda, Jiménez, and Díaz \(2012\)](#). Since city fixed effects can be measured only in relative terms (across cities), we focus on deviations from the average city fixed effect. The corresponding results are given in the Online Appendix Table A.2, where city fixed effects on profit margins range between  $-31.8$  and  $32.2$ , suggesting that city characteristics are highly effective in explaining cross-route profit margin differences; relatively high  $R$ -squared values support these results.

---

<sup>10</sup>This result is also consistent with the trade-off between long-distance flights being less substitutable (i.e., having higher profit margins) and requiring a larger share of a passenger's budget (i.e., corresponding to a higher price elasticity and thus having lower profit margins), where these two forces apparently cancel each other out.

It is implied that flying to/from a particular city may be more or less costly for passengers with respect to other cities in terms of the profit margins paid. Based on the estimated city fixed effects in the Online Appendix Table A.2, top ten cities with the lowest and with the highest profit margins are given in Table 5. As is evident, cities such as Albany, GA or Atlantic City, NJ are the cities with lower profit margins, whereas cities such as Redding, CA or Panama City, FL are those with higher profit margins, on average across routes.

## 6 Concluding Remarks and Policy Implications

Estimation of profit margins through price elasticity measures requires careful identification of shocks and their impact on prices and quantities. This paper has used a structural vector autoregression model to identify shocks on the number of passengers and their impact on airfares by using quarterly data on the U.S. domestic airline industry at the route level. Estimation results have suggested higher measures of price elasticity of demand with respect to the literature such that the U.S. domestic airline industry has an average annual profit margin of about 13.3%, with a range between 2.7% and 42.9%. These average values are in line with industry-level profit data from the U.S., supporting the estimation and identification methodology in this paper.

Going back to the question asked at the beginning of this paper, it turns out that the route between Seattle, WA and Yakima, WA with an average airfare of \$103 has experienced annual profit margins of about 22.1%, while the route between New York City, NY and Monterey, CA with an average airfare of \$402 has experienced annual profit margins of about 9.9%. Therefore, the higher airfare (with a distance of 2,596 miles) has experienced

profit margins less than half of those experienced by the lower airfare (with a distance of only 103 miles), suggesting that consumer welfare has been higher with the higher airfare (or the longer distance). This result is not specific to this particular route; it has been shown by considering all routes that higher profit margins are associated with lower airfares, higher market shares or shorter distance measures. It is implied regarding consumer welfare that consumers benefit more from U.S. domestic routes with higher airfares, longer distances or lower airline market shares.

Regarding airline profits, it is implied that there are higher annual profit opportunities in routes with lower airfares, higher airline market shares or shorter distances. City characteristics have also shown to be important determinants of profit margins, where cities such as Albany, GA or Atlantic City, NJ are the cities with lowest profit margins, whereas cities such as Redding, CA or Panama City, FL are those with highest profit margins, on average across routes. However, when annual profit margins have been regressed on all variables at the same time to avoid any omitted variable bias, the coefficient of distance becomes insignificant, consistent with the trade-off between long-distance flights being less substitutable (i.e., having higher profit margins) and requiring a larger share of a passenger's budget (i.e., corresponding to a higher price elasticity and thus having lower profit margins), where these two forces apparently cancel each other out.

The results in this paper that correspond to higher measures of price elasticity of demand (and thus lower profit margins) with respect to the literature have important policy implications. Specifically, if authorities impose regulations or taxes to avoid excessive usage of market power by airlines, the results of this paper imply a higher response of passengers with respect to the existing literature for the average domestic route, suggesting that aviation

policies would be more effective in general. It is also implied that the burden of a potential policy change would be shared between airlines and passengers, which is important from a consumer welfare perspective.

Since profit margins of airlines increase (and thus measures of price elasticity of demand decrease) with the market share and they decrease with airfare and the number of passengers across domestic routes, there are also route-specific policy implications. In particular, any aviation regulation or tax would be more effective in domestic routes with higher airfares, higher number of passengers or lower market shares. Therefore, aviation authorities can focus more on these particular domestic routes if they would like to have effective policies to protect consumer welfare.

**Table 1 - Descriptive Statistics**

	Airfare (\$)	Passenger (#)	Market Share (%)	Distance
Mean	226	313	55	1,066
Median	227	82	53	933
Minimum	96	16	24	94
Maximum	434	19,336	100	2,724
Std. Dev.	48	828	16	593

Notes: Airfares are in U.S. dollars. Passenger numbers are represented as average per day.

Market share represents the share of the largest airline in percentage terms. Distance

represents nonstop flight distance in miles. Std. Dev. stands for standard deviation.

**Table 2 - Summary of Estimation Results**

	Profit Margin (%)	Price Elasticity of Demand
Mean	13.264	9.009
Median	12.381	8.077
Minimum	2.722	2.333
Maximum	42.872	39.567
Standard Deviation	5.522	4.249

Notes: Values represent the distribution across routes. The values represent estimates obtained one year after a shock on the number of passengers. City-pair specific estimation results are given in the Online Appendix.

**Table 3 - Cross-Route Estimation Results (OLS)**

Dependent Variable: Profit Margins (%)					
	(1)	(2)	(3)	(4)	(5)
Log Airfare	-1.440** (0.486)				-2.823** (0.940)
Log Passenger		-0.185 (0.161)			-1.226*** (0.252)
Market Share			3.133*** (0.693)		2.725** (0.957)
Log Distance				-0.910*** (0.172)	-0.321 (0.300)
City Fixed Effects	YES	YES	YES	YES	YES
Sample Size	2992	2992	2992	2992	2992
Adj. <i>R</i> -Squared	0.329	0.318	0.316	0.321	0.329

Notes: Standard errors are in parentheses. +, \*, \*\*and \*\*\*represent significance at the 10%, 5%, 1% and 0.1% levels, respectively.

**Table 4 - Cross-Route Estimation Results (TSLS)**

Dependent Variable: Profit Margins (%)			
	(1)	(2)	(3)
Log Airfare	-3.788*** (0.723)	-4.399*** (1.136)	-0.947+ (0.566)
Log Passenger		-1.529*** (0.309)	
Market Share		3.177*** (0.774)	
City Fixed Effects	YES	YES	YES
Sample Size	2992	2992	2992

Notes: Standard errors are in parentheses. +, \*, \*\* and \*\*\* represent significance at the 10%, 5%, 1% and 0.1% levels, respectively.

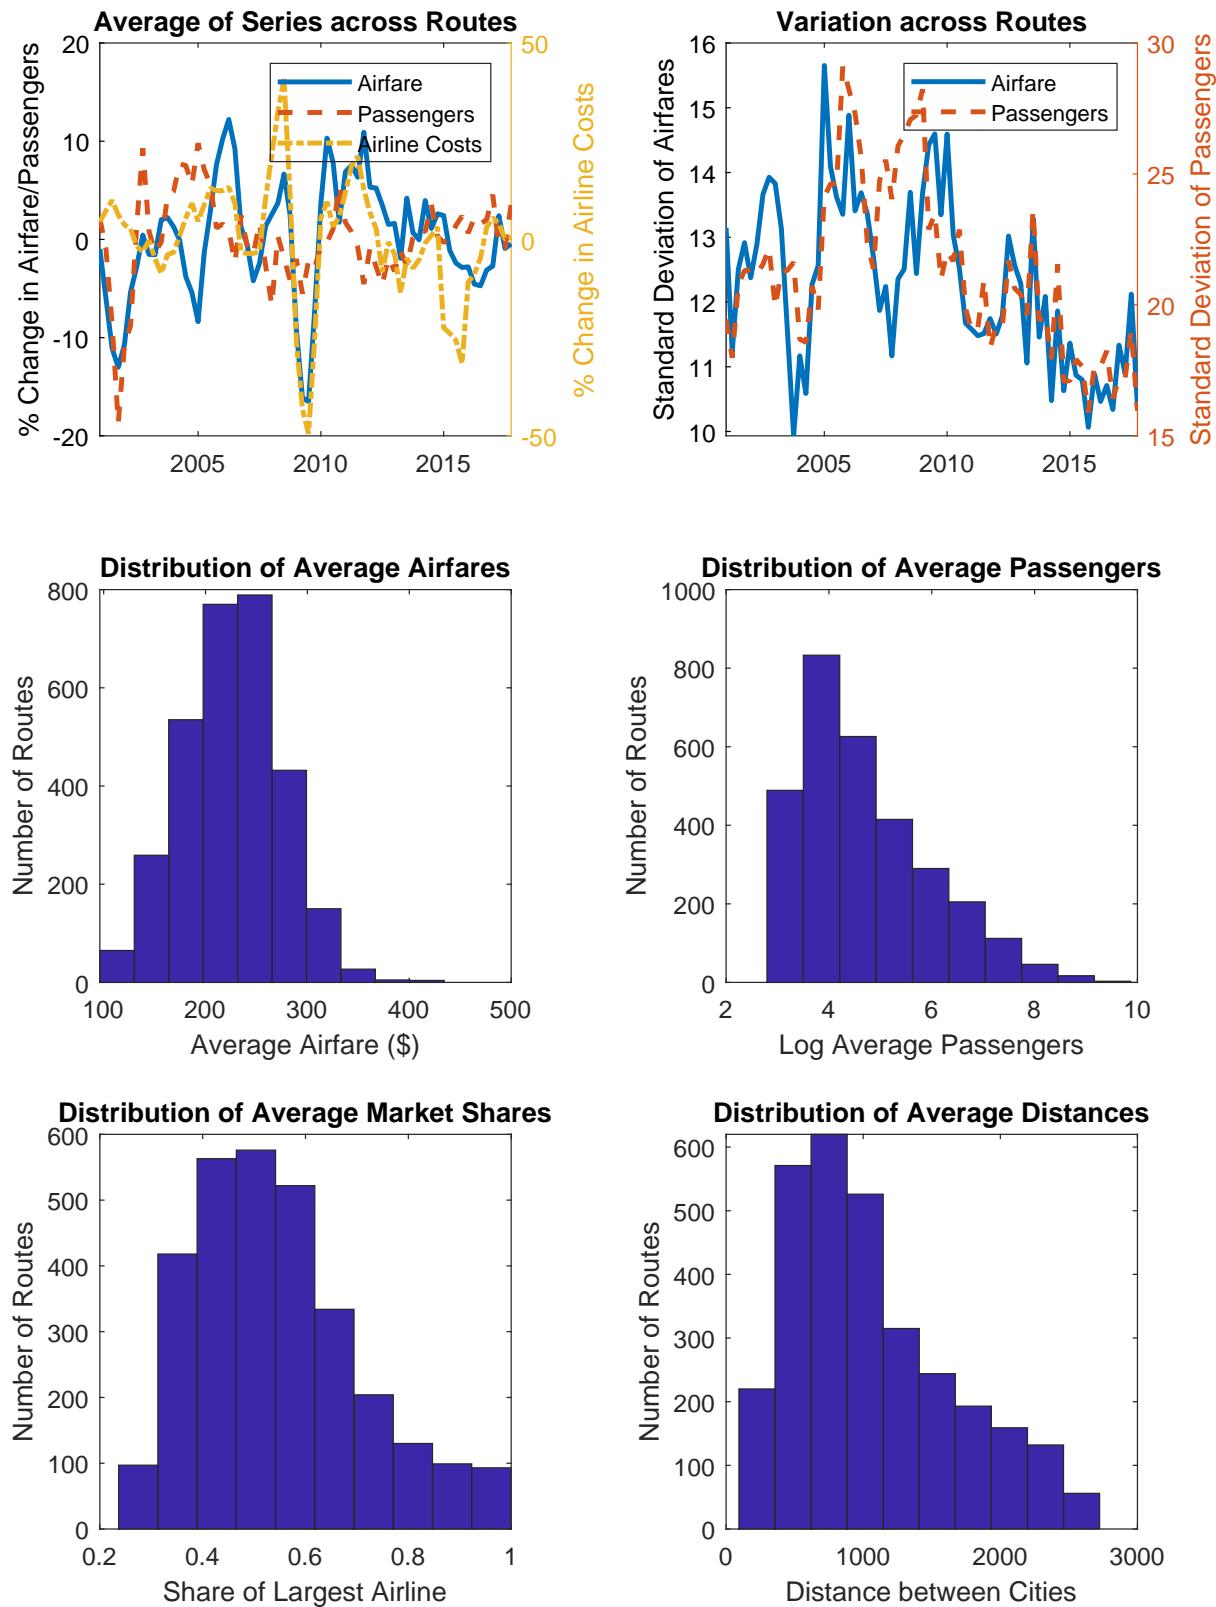

Regressions (1) and (2) instrument log airfare with log distance, whereas regression (3) instruments log airfare with log distance, .  
log passenger and market share

**Table 5 - Top Ten Cities**

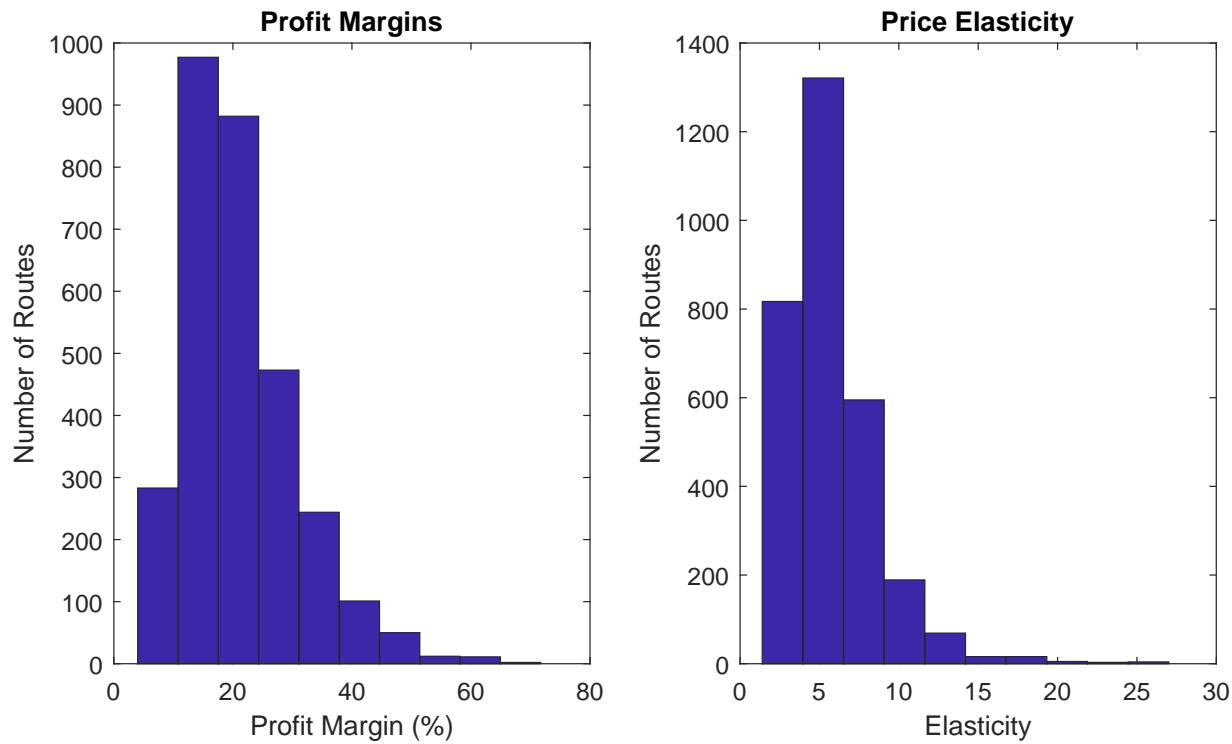

Cities with Lowest Profit Margins	Cities with Highest Profit Margins
Albany, GA	Redding, CA
Atlantic City, NJ	Panama City, FL
Albuquerque, NM	Toledo, OH
Albany, NY	Laredo, TX
Lawton/Fort Sill, OK	Key West, FL
Amarillo, TX	New Bern/Morehead/Beaufort, NC
Dothan, AL	Sun Valley/Hailey/Ketchum, ID
Appleton, WI	Wausau/Mosinee/Stevens Point, WI
Bismarck/Mandan, ND	Gainesville, FL
Abilene, TX	Walla Walla, WA

Notes: These lists are based on the city fixed effects given in the Online Appendix Table A.2.

Notes: The results represent the annual estimates obtained one year after the shock. Estimations have been achieved individually for each city pair. Median, Lower and Upper represent the median, 16th percentile and 84th percentile of the Bayesian draws that satisfy the condition of the inverse price elasticity of demand being in the unit interval.

Laredo, TX	22.53
Toledo, OH	23.33
Panama City, FL	24.87
Redding, CA	32.24

Notes: Numbers are in percentage terms. The results represent the estimates based on profit margins obtained one year after the shock. The cross-route regression used to obtain these results has the dependent variable of profit margins (%), and the independent variables of city fixed effects only. The regression has an R-squared value of 0.402.
